Safer, Easier Management of Difficult Bile Duct Stone Cases

Introducing the StoneMasterV, a new device that enables you to perform both EST and EPLBD procedures with a single device

What is EPLBD?

Over the past few years, endoscopic papillary large-balloon dilation (EPLBD) — which, as its name implies, uses a large balloon — has become an increasingly popular technique for the extraction of large bile duct stones. It is important to point out that we are referring at least three EPLBD techniques for the treatment of the papilla. The first is the original EPLBD technique described by Ensrud et al. for the first time in 2003. Their paper specified that the indication for EPLBD should be restricted to cases where stone extraction would be difficult even when EST had been performed and introduced the execution of EPLBD on papilla that had been treated with EST. What was most remarkable about this paper was that the authors specified the incision length of EST from the papillary orifice to the vicinity of the hooding fold, ensuring that EST was successfully performed. The second EPLBD technique is for cases recurring after EST has been performed. In this case, EPLBD is performed in a separate session following EST (irrespective of the time elapsed since EST was originally performed) in cases where successful extraction of the stone was not possible with EST alone. Both the first and second EPLBD techniques are quite similar in that both involve EST and the third and final technique is EPLBD without EST.

Is EST necessary in EPLBD?

First of all, let’s examine the mechanism of the original EPLBD technique based partly on my opinion. The purpose of dilation of the papillary orifice using a large balloon is to enlarge the bile duct opening to facilitate stone extraction. When a balloon for standard endoscopic papillary balloon dilation (EPBD) — which has a diameter of about 8 mm — is used, the papilla dilated by the balloon — uniformly dilated in many cases — can be observed quite clearly. Even if the balloon is inflated to its maximum, the proximal side of the bile duct does not cross over the hooding fold. In other words, even when partial tearing of the papillary sphincter occurs, there is no tearing of the papilla itself. On the other hand, in papillary dilation using a large balloon measuring 15 mm or 18 mm in diameter, the papillary opening is exces-
As for EPLBD without EST, there have been some prospective and retrospective studies, but none can be considered sufficiently reliable at this point, leaving open the question as to whether EPLBD with intentional omission of EST can be justified or not. At our hospital, when EST could not be performed for some reason in one clinical case of severe pancreatitis, the patient did not survive. Therefore, we recommend that EPLBD is being performed following a previous EST (we call it EPLBD-EST to differentiate it from simple EPLBD) whenever possible to ensure that EPLBD can be regarded as safe. Interestingly, even Dr. DiSario, who cancelled his RCTs due to a fatal EPLBD case and subsequently denied the efficacy of EPLBD in his paper, has said that he could support EPLBD after EST for the same reason.

**Actual EPLBD procedure and the StoneMasterV**

Now, let’s see how EPLBD following EST actually works when the StoneMasterV is used. Before the introduction of this device, it was necessary to withdraw the sphincterotome after EST, while leaving the guidewire in place, and then insert a large balloon — one which would exactly fit the bile duct diameter and the stone diameter. Common practice also includes preparing a large balloon in advance. Though in some cases, the balloon had the wrong size and a second one had to be utilized. Conclusively, this approach has a negative costs and time performance. To solve these problems, we developed the StoneMasterV sphincterotome with a large balloon in cooperation with Olympus, which took us eight years. This device is an all-in-one sphincterotome for difficult stone management, featuring a 7-mm distal tip and a 20, 25, or 30-mm cutting wire length, — equipped with a 40-mm long — large balloon on the proximal side of the cutting portion (Fig. 1).

Thanks to this design, you can perform EPLBD by advancing in the sheath of the sphincterotome continuously after EST. Unlike other models, you can adjust the size of the large balloon from 12 mm to 18 mm controlling the inflation pressure, making it truly the world’s first “all-in-one” large balloon for EPLBD (for your information, the inflated balloon diameters are 12 mm, 15 mm, and 18 mm at 0.5 atm., 2.0 atm., and 3.5 atm., respectively).

The following are difficult bile duct stone cases that were managed with the StoneMasterV.

1. **Recurrent stacked stones**

The selective cholangiography we performed for this case showed that the bile duct was filled as far as the porta hepatis with stones ranging in size from 10 to 15 mm (Fig. 2a). In therapeutic ERCP at our hospital, we normally perform wire-guided cannulation (WGC) after the execution of EST, so we performed selective bile duct cannulation using the StoneMasterV from the start. Although EST was performed by the previous doctor, it was insufficient, so we made an additional incision using the Endo Cut mode (Fig. 2b) until we reached the point where bile started flowing out naturally. Subsequently, the sheath of the StoneMasterV was advanced, the large balloon portion was inserted into the bile duct (Fig. 2c), and the balloon was inflated with a contrast medium diluted by half. The balloon diameter was set to approximately 17 mm at about 2.5 atm., making it roughly the same diameter as the stones and the bile duct. The balloon was kept inflated for about 10 seconds and then slowly deflated. It was confirmed that there was no bleeding (Fig. 2d).

After the StoneMasterV was pulled out without resistance, a wire-guided mechanical lithotripsy basket (Single Use Mechanical Lithotriptor V BML-V437QR-30; Olympus Medical Systems) (Fig. 3a) was used to simultaneously extract 3 stones in the lower bile duct (Fig. 2e). More stones were subsequently extracted from the lower bile duct without crushing. Finally, we grasped a giant stone in the upper bile duct and tried to extract it. However, it became impacted at the papilla. After pushing it back to the middle bile duct, we crushed it and then extracted it (Fig. 2f). Impaction of stones is possible whenever multiple stones are grasped — regardless of whether they are large or small, so it is a good idea to use a basket lithotripter with stone crushing capability. Following stone extraction, no residual stones were observed under fluoroscopy with a contrast-filled balloon (Fig. 2g).

2. **Post-gastrectomy Billroth-I reconstruction, giant stones**

Although we experienced difficulty in viewing the site from the right front (Fig. 3a) because this was a Billroth-I case, we started the procedure using the StoneMasterV to perform selective bile duct cannulation. Then we performed further bile duct cannulation with WGC. Under cholangiography, we observed 3 stones ranging in size from 15 to 20 mm in the curved bile duct (Fig. 3b). The bile duct axis is often curved in Billroth-I cases, so we performed EST precisely in the 12 o’clock direction (Fig. 3c). We continued to advance the sheath of the StoneMasterV, inserted the large balloon portion in the bile duct, and inflated the balloon (Fig. 3d). Taking the diameters of the stones into consideration, we gradually increased the balloon diameter up to 18 mm at 3.5 atm. (Fig. 3e). In this case, the lower bile duct remained edematous, making insertion of the lithotripsy basket (Single Use Mechanical Lithotriptor V BML-V437QR-30; Olympus Medical Systems) (Fig. 3f) to crush stones difficult. We therefore used the StoneMasterV sphincterotome with a large balloon in cooperation with Olympus, which took us eight years. This device is an all-in-one sphincterotome for difficult stone management, featuring a 7-mm distal tip and a 20, 25, or 30-mm cutting wire length, — equipped with a 40-mm long — large balloon on the proximal side of the cutting portion (Fig. 1).

Thanks to this design, you can perform EPLBD by advancing in the sheath of the sphincterotome continuously after EST. Unlike other models, you can adjust the size of the large balloon from 12 mm to 18 mm controlling the inflation pressure, making it truly the world’s first “all-in-one” large balloon for EPLBD (for your information, the inflated balloon diameters are 12 mm, 15 mm, and 18 mm at 0.5 atm., 2.0 atm., and 3.5 atm., respectively).

The following are difficult bile duct stone cases that were managed with the StoneMasterV.
